Spin: Introduction*

Patrick Trentin patrick.trentin@unitn.it http://disi.unitn.it/~trentin

Formal Methods Lab Class, Feb 26, 2016

^{*}These slides are derived from those by Stefano Tonetta, Alberto Griggio, Silvia Tomasi, Thi Thieu Hoa Le, Alessandra Giordani, Patrick Trentin for FM lab 2005/15

Course Overview

Course: covers two tools for model checking and formal verification

- Part I: Spin
- Part II: NUXMV

```
Slides + Solutions: http://disi.unitn.it/~trentin

⇒ the slides' content will be updated wrt. last year
```

Exam:

- examples + solutions will be provided
- short manuals of both tools available during exam
 - ⇒ thus: code that does not even compile is significantly penalized

Contents

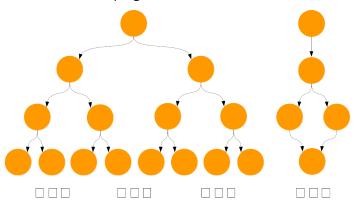

- Course Overview
- 2 Introduction to SPIN
- PROMELA examples
 - Hello world!
 - Producers/Consumers
 - Mutual Exclusion
- 4 SPIN's Output

The Spin (= \underline{S} imple \underline{P} romela \underline{In} terpreter) model checker

- Tool for formal verification of distributed and concurrent systems (e.g. operating systems, data communications protocols).
 - Developed at Bell Labs.
 - In 2002, recognized by the ACM with Software System Award (like Unix, TeX, Smalltalk, Postscript, TCP/IP, TcI/Tk).
 - Automated tools convert programs written in Java or in C into SPIN models.
- The modelling language is called PROMELA.
- Spin has a graphical user interface, ISPIN.
- Materials:
 - Homepage: http://spinroot.com/spin/whatispin.html
 - Manual: http://spinroot.com/spin/Man/index.html

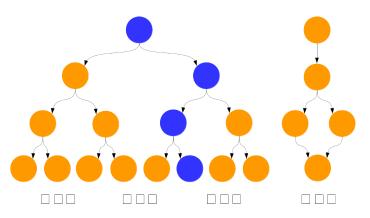

PROMELA (= $\underline{Pro}tocol/\underline{Pro}cess \underline{Me}ta \underline{La}nguage)$

- Promela is suitable to describe concurrent systems:
 - dynamic creation of concurrent processes.
 - (synchronous/asynchronous) communication via message channels.
- Possible executions of a program

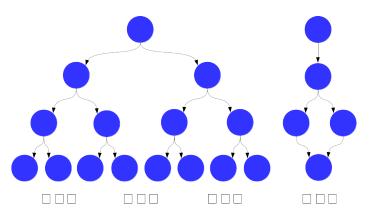

Simulation

- can be random, interactive or guided.
- \bullet useful for inspection of the $\ensuremath{\mathrm{PROMELA}}$ model
- not useful for finding bugs!

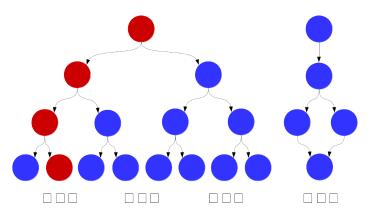

Verification

- check every execution looking for a counterexample for a given property
- can be exhaustive or approximate

Verification: counterexample

- witnesses a violation of a given property
- stored in the current directory with ".trail" extension
- can be replayed with -t option

Basic commands

- To simulate a program: spin system.pml
- Interactively: spin -i system.pml
- To generate a verifier (pan.c): spin -a system.pml
- To run a guided simulation: spin -t model.pml

To run ISPIN: ispin model.pml

Useful commands:

- To see available options: spin --
- To display processes moves at each simulation step: spin -p system.pml
- To display values of global variables: spin -g system.pml
- To display values of local variables: spin -I -p system.pml

Contents

- Course Overview
- 2 Introduction to SPIN
- PROMELA examples
 - Hello world!
 - Producers/Consumers
 - Mutual Exclusion
- 4 Spin's Output

Hello world!

```
active proctype main()
{
    printf("hello world\n")
}
```

- active instantiates one process of the type that follows.
- **proctype** denotes that *main* is a process type.
- main identifies the process type, it's not a keyword.
- Note that ';' is missing after printf:
 - ';' is a statement separator, not a statement terminator.

Hello world! Alternative

- init is a process that initializes the system.
- Initially just the initial process is executed.

Hello world! Alternative

- init is a process that initializes the system.
- Initially just the initial process is executed.

Simulation:

```
> spin hello.pml
         hello world
1 process created
```

One process was created to simulate the execution of the model.

Producers/Consumers

```
mtype = \{ P, C \};
mtype turn = P;
active proctype producer(){
        do
        :: (turn == P) ->
                 printf("Produce\n");
                 turn = C
        od
}
active proctype consumer(){
       do
       :: (turn == C) ->
                 printf("Consume\n");
                 turn = P
       od
```

Feb 26, 2016

Producers/Consumers (Language Details)

- mtype defines symbolic values (similar to an enum declaration in a C program).
- turn is a global variable.
- do ... od (do-statement) defines a loop.
- Every option of the loop must start with '::'.
- (turn == P) is the guard of the option.
- A break/goto statement can break the loop.
- -> and; are equivalent
 (-> indicates a causal relation between successive statements).
- If all guards are false, then the process blocks (no statement can be executed).
- If multiple guards are true, we get non-determinism.

Producers/Consumers

Simulation:

```
> spin prodcons.pml | more
Produce
Consume
Produce
Consume
Produce
```

Consume

Produce

Consume

Produce

Consume

. . .

There can be multiple **running instances** of the same *proctype*:

There can be multiple **running instances** of the same *proctype*:

Concurrent execution: after each (atomic) statement, a new process can be (randomly) scheduled for execution.

```
> spin -i prodcons2_flaw.pml
Select a statement
choice 3: proc 1 (producer) prodcons2_flaw.pml:7 (state 4) [((turn==P))]
choice 4: proc 0 (producer) prodcons2_flaw.pml:7 (state 4) [((turn==P))]
Select [1-4]: 3
Select a statement
choice 3: proc 1 (producer) prodcons2_flaw.pml:9 (state 2) [printf('Produce\\n')]
choice 4: proc 0 (producer) prodcons2_flaw.pml:7 (state 4) [((turn==P))]
Select [1-4]: 3
         Produce
Select a statement
choice 3: proc 1 (producer) prodcons2_flaw.pml:10 (state 3) [turn = C]
choice 4: proc 0 (producer) prodcons2_flaw.pml:7 (state 4) [((turn==P))]
Select [1-4]: 4
Select a statement
choice 3: proc 1 (producer) prodcons2_flaw.pml:10 (state 3) [turn = C]
choice 4: proc 0 (producer) prodcons2_flaw.pml:9 (state 2) [printf('Produce\\n')]
Select [1-4]:
```

Problem: Both processes can pass the guard (turn == P) and execute printf("Produce") before turn is set to C.

A correct declaration for the producer:

- assert: if expression is false (i.e. zero) then abort the program, else ignored.
- _pid is a predefined, local, read-only variable of type pid that stores the unique ID of the process.

Definition of request:

```
inline request(x, y, z) {
     atomic { x == y -> x = z; who = _pid }
}
```

- inline functions like C macros.
 - the body is directly pasted into the body of a proctype at each point of invocation.
- **atomic**: prevents the scheduler from changing the running process until all the statements are executed.
 - no interleaving with statements of other processes!
- The executability of the atomic sequence is determined by the first statement.
 - i.e. if x==y is true then the atomic block is executed.

File prodcons2.pml: $mtype = \{ P, C, N \};$ mtype turn = P; pid who; ... // request inline release(x, y) { atomic { x = y; who = 0 } } ... // proctype producer active [2] proctype consumer() do :: request(turn, C, N) -> printf("Consume %d\n", _pid); assert(who == _pid); release(turn, P) od

Simulation:

```
> spin prodcons2.pml | more
           P1
                    C3
      P0
                    СЗ
           P1
                    СЗ
           P1
                C2
      P0
                    C3
           P1
```

Simulation can detect errors:

```
init { assert(false) }
> spin false.pml
spin: line   1 "false.pml", Error: assertion violated
spin: text of failed assertion: assert(0)
#processes: 1
   1:   proc   0 (:init:) line   1 "false.pml" (state 1)
1 process created
```

However, simulation can not prove that the code is bug-free!

A verifier checks that an assertion is never violated.

We use Spin to generate the verifier of *prodcons.pml*:

```
> spin -a prodcons2.pml
> gcc -o pan pan.c
> ./pan
Full statespace search for:
       never claim
                                - (none specified)
        assertion violations
                                - (not selected)
        acceptance cycles
        invalid end states
State-vector 28 byte, depth reached 7, errors: 0
```

Back to the flawed Producers/Consumers

```
mtype = { P, C };
                                        active [2] proctype consumer()
mtype turn = P;
                                          dο
                                             :: (turn == C) ->
int msgs;
                                                printf("Consume\n");
                                                msgs--;
active [2] proctype producer()
                                                turn = P
                                          od
  do
    :: (turn == P) ->
       printf("Produce\n");
       msgs++;
                                        active proctype monitor() {
       turn = C
                                          assert(msgs >= 0 && msgs <= 1)
  od
                                        }
```

> spin -a prodcons2_flaw_msg.pml && gcc -o pan pan.c && ./pan

Producers/Consumers Extended (Trail File)

Trail File

 ${\tt prodcons2_flaw.pml.trail} \ contains \ {\tt SPIN's} \\ transition \ {\tt markers} \ corresponding \ to \ the \ contents \\ of \ the \ stack \ of \ transitions \ leading \ to \ error \ states \\$

Meaning:

- Step number in execution trace
- Id of the process moved in the current step
- Id of the transition taken in the current step

```
1:1:0
2:1:1
3:1:2
4:1:3
5:3:8
6:3:9
7:3:10
```

-4:-4:-4

10	:3	:11
11	:2	:10

```
12:4:16
```

The Mutual Exclusion problem

```
General algorithm
active [2] proctype mutex()
{
again:
        /* trying section */
        cnt++;
        assert(cnt == 1);
                                   /* critical section */
        cnt--;
        /* exit section */
        goto again
```

The Mutual Exclusion problem (First tentative)

```
bit flag; /* signal entering/leaving the section */
byte cnt; /* # procs in the critical section */
active [2] proctype mutex() {
again:
  flag != 1; /* It models "while (flag == 1) wait!" */
  flag = 1;
  cnt++:
  assert(cnt == 1):
  cnt--;
  flag = 0;
  goto again
```

Feb 26, 2016

The Mutual Exclusion problem (First tentative)

```
bit flag; /* signal entering/leaving the section */
byte cnt; /* # procs in the critical section */
active [2] proctype mutex() {
again:
  flag != 1; /* It models "while (flag == 1) wait!" */
  flag = 1;
  cnt++:
  assert(cnt == 1):
  cnt--;
  flag = 0;
  goto again
```

Assertion violation: Both processes can pass the flag != 1 before flag is set to 1.

The Mutual Exclusion problem (Second tentative)

```
bit x, y; /* signal entering/leaving the section */
byte cnt;
active proctype A() {
                                 active proctype B() {
again:
                                 again:
  /* A waits for B to end */
                                   v = 1;
  x = 1;
                                   x == 0;
  v == 0;
                                   cnt++;
  cnt++:
                                   /* critical section */
  /* critical section */
                                   assert(cnt == 1);
  assert(cnt == 1);
                                   cnt--;
  cnt--;
                                   v = 0;
  x = 0:
                                   goto again
  goto again
```

The Mutual Exclusion problem (Second tentative)

```
bit x, y; /* signal entering/leaving the section */
byte cnt;
active proctype A() {
                                 active proctype B() {
again:
                                 again:
  /* A waits for B to end */
                                   y = 1;
  x = 1;
                                   x == 0;
  v == 0;
                                   cnt++;
  cnt++:
                                   /* critical section */
  /* critical section */
                                   assert(cnt == 1);
  assert(cnt == 1);
                                   cnt--;
  cnt--;
                                   v = 0;
  x = 0:
                                   goto again
  goto again
```

Invalid-end-state: Both processes can execute x = 1 and y = 1 at the same time and will then be waiting for each other.

Dekker/Dijkstra algorithm

```
/* trying section */
flag[i] = true;
do
   :: flag[j] ->
      if
         :: turn == j ->
            flag[i] = false;
             !(turn == j);
             flag[i] = true
         :: else -> skip
      fi
   :: else ->
      break
od;
```

Dekker/Dijkstra algorithm

```
/* trying section */
flag[i] = true;
do
                                       /* initialization */
   :: flag[j] ->
                                       pid i = _pid;
      if
                                       pid j = 1 - pid;
         :: turn == j ->
            flag[i] = false;
            !(turn == j);
                                       /* exit session */
            flag[i] = true
                                       turn = j;
         :: else -> skip
                                       flag[i] = false;
      fi
   :: else ->
      break
od;
```

Dekker/Dijkstra algorithm

```
Verification:
> spin -a dekker.pml
> cc -o pan pan.c
> ./pan
Full statespace search for:
        never claim
                                - (none specified)
        assertion violations
                                - (not selected)
        acceptance cycles
        invalid end states
                                +
State-vector 20 byte, depth reached 67, errors: 0
```

Peterson algorithm

Peterson Implementation:

```
/* trying session */
        flag[i] = true;
        turn = i;
        !(flag[j] && turn == i) ->
    /* exit session */
        flag[i] = false;
Verification:
> spin -a peterson.pml
> cc -o pan pan.c
> ./pan
State-vector 20 byte, depth reached 41, errors: 0
```

Feb 26, 2016

Exercises

- Simulate you_run2.pml and you_run3.pml.
- Verify prodcons3.pml.
- Verify mutex_flaw.pml.
- Delete "turn==i" in Peterson and verify the correctness.

```
> ./pan
pan: assertion violated ((x!=0)) (at depth 11)
pan: wrote model.pml.trail
```

Assertion Violation

- SPIN has found a execution trace that violates the assertion
- the generated trace is 11 steps long and it is contained in model.pml.trail

```
(Spin Version 6.0.1 -- 16 December 2010) + Partial Order Reduction
```

- Version of Spin that generated the verifier
- Optimized search technique

```
Full statespace search for:

never-claim - (none specified)

assertion violations +

acceptance cycles - (not selected)

invalid endstates +
```

- Type of search: exhaustive search (Bitstate search for approx.)
- No never claim was used for this run
- The search checked for violations of user specified assertions
- The search did not check for the presence of acceptance or non-progress cycles
- The search checked for invalid endstates (i.e., for absence of deadlocks)

State-vector 32 byte, depth reached 13, errors: 0

- The complete description of a global system state required 32 bytes of memory (per state).
- The longest depth-first search path contained 13 transitions from the initial system state.
 - ./pan -mN set max search depth to N steps
- 3 No errors were found in this search.

74 states, stored
30 states, matched
104 transitions (= stored+matched)
1 atomic steps
1.533 memory usage (Mbyte)

- A total of 74 unique global system states were stored in the statespace.
- In 30 cases the search returned to a previously visited state in the search tree.
- 3 A total of 104 transitions were explored in the search.
- One of the transitions was part of an atomic sequence.
- 5 Total memory usage was 1.533 Megabytes,

```
unreached in proctype ProcA
    line 7, state 8, "Gaap = 4"
        (1 of 13 states)
unreached in proctype :init:
    line 21, state 14, "Gaap = 3"
        (1 of 19 states)
```

Meaning

A listing of the state numbers and approximate line numbers for the basic statements in the specification that were not reached \Rightarrow since this is a full statespace search, these transitions are effectively unreachable (dead code).

error: max search depth too small

Meaning

It indicates that search was truncated by depth-bound (i.e. the depth bound prevented it from searching the complete statespace).

./pan -m50
 sets a bound on the depth of the search

Nota Bene

When the search is bounded, SPIN will not be exploring part of the system statespace, and the omitted part may contain property violations that you want to detect \Rightarrow you cannot assume that the system has no violations!
