Fourth International Workshop on
Ontology Matching (OM-2009)
October, 2009

OUTLINE

- The role of taxonomic structure preservation in ontology alignment
- Order theoretical approach to semantic hierarchy alignment
- 2008 Anatomy: lower distance discrepancy only
- Participation in evaluation for OAEI 2009
 - 2009 Benchmnark
 - 2009 Anatomy

SEMANTIC HIERARCHIES

Ubiquitous, universal: Transitive, non-symmetric links

- Subsumptive, inheritance taxonomies: *is-a*
- Merenomic, compositional: *part-of*
- Implies, precedes, causes

Claim: Cores of ontologies, taxonomies, computational lexicons, typing systems

- Comprise the bulk of links in real-world ontological knowledgebases: 80 – 90% of links
- Becoming large: 10^5 – 10^7

Challenge: Identify/establish technology for key tasks:

- Classification, categorization, clustering
- Induction from source data
- Navigation, anomaly detection
- Visualization
- Link analysis, search, retrieval
- Merger, linkage, interoperability

STRUCTURAL PRESERVATION IN ONTOLOGY ALIGNMENT

- Taxonomy alignment cast as (single- or multi-valued) mapping between two semantic hierarchies
- Relative size, structure, domains, impart different properties:
 - More partial in one direction or other
 - More concentrated in one portion or another
 - Take nodes “close together” in one hierarchy to nodes “far apart” in the other
 - Take nodes in one structural relationship (e.g. parent-child) into another (e.g. sibling)
- We can measure the *smoothness* of an alignment
- *Smooth mapping neither necessary nor sufficient to be a good mapping*
 - Strong correlation of smoothness with P, R, F promises an *automatic* predictor of alignment quality independent of gold standard
 - *Knowledge of mapping properties useful:*

Ontology Aligners: Homogeneous alignments within one domain

Ontology Designers: Given a determinate alignment against a reference ontology

ORDER THEORETICAL SEMANTIC HIERARCHY ALIGNMENT

Hierarchies: Finite, bounded, partially ordered sets (posets) $\mathcal{P} = \langle P, \leq \rangle$

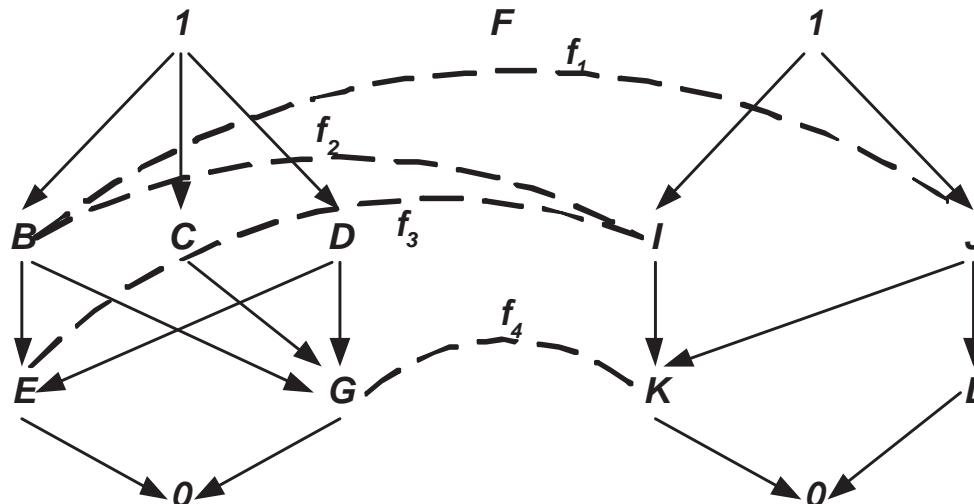

Alignment Relation: $F \subseteq P \times P'$ is a collection of pairs $\vec{f} = \langle a, a' \rangle \in F$, for $\mathcal{P} := \langle P, \leq \rangle, \mathcal{P}' := \langle P', \leq' \rangle$

Links, Anchors: $\vec{f} \in F$

$$Q := \{a \in P, \exists a' \in P', \langle a, a' \rangle \in F\} \subseteq P$$

$$Q' := \{a' \in P', \exists a \in P, \langle a, a' \rangle \in F\} \subseteq P',$$

Counts: $m := |Q|, m' := |Q'|$, and $N := |F| \leq mm'$.

STRUCTURAL PRESERVATION CRITERIA

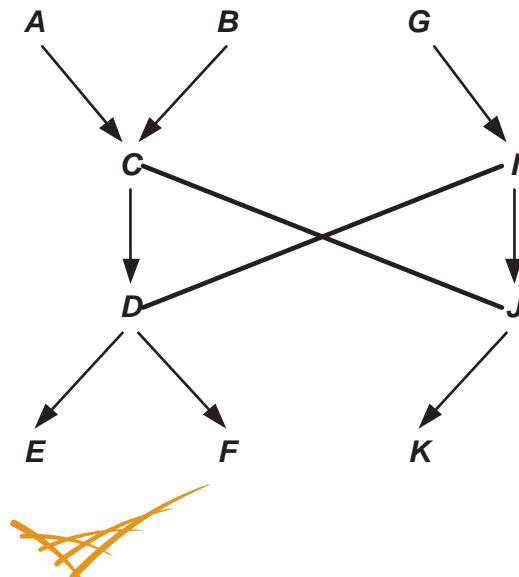

Approach: Not *relative* measure of alignment to gold standard
Rather an *inherent* or *independent* measure of the alignment

Twist, Order Discrepancy: a, b should have the same structural relations in \mathcal{P} as a', b' in \mathcal{P}'

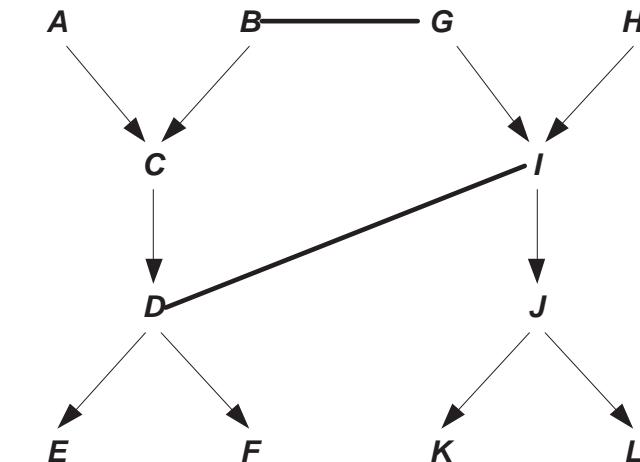

- **Comparable:** Ancestor-successor, parent-child
- **Non-comparable:** Sibling, cousin, etc.

Stretch, Distance Discrepancy: Relative distance between $a, b \in P$ should be the same as $a', b' \in P'$

Twist but no stretch

Stretch but no twist

SIMPLE ORDER DISTANCE

Not path-counting

Upset (Ancestors), Downset (Descendants):

$$\uparrow a := \{b \geq a\}, \quad \downarrow a := \{b \leq a\}$$

Upper and Lower Bounds: For a set of nodes $Q \subseteq P$

$$\text{Min}(Q) := \{a \in Q : \forall b \in Q, b < a\} \subseteq P,$$

$$\text{Max}(Q) := \{a \in Q : \forall b \in Q, b > a\} \subseteq P.$$

Generalized Join and Meet:

$$a \vee b := \text{Min}(\uparrow a \cap \uparrow b) \subseteq P$$

$$a \wedge b := \text{Max}(\downarrow a \cap \downarrow b) \subseteq P,$$

Upper Distance:

$$d_u(a, b) = |\uparrow a| + |\uparrow b| - 2 \max_{c \in a \vee b} |\uparrow c|$$

Lower Distance:

$$d_l(a, b) = |\downarrow a| + |\downarrow b| - 2 \max_{c \in a \wedge b} |\downarrow c|$$

Example:

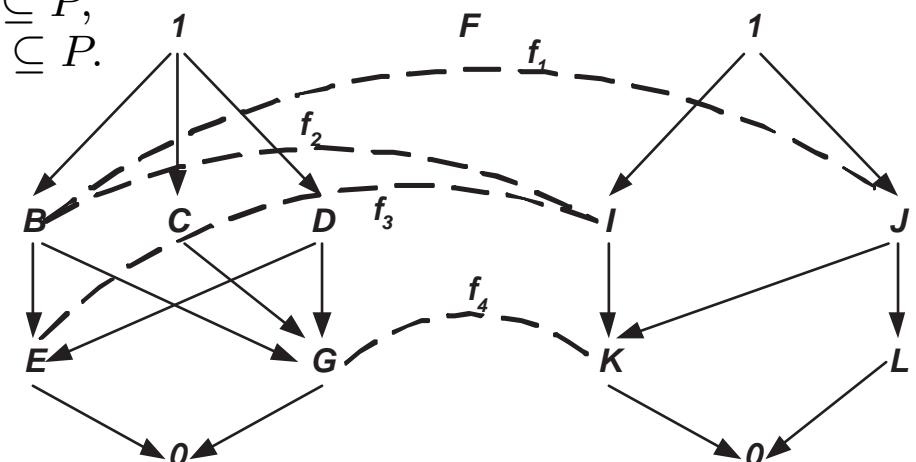

$$\uparrow E = \{1, B, D, E\},$$

$$\uparrow E \cap \uparrow G = \{1, B, D\}$$

$$E \vee G = \{B, D\}$$

$$d_u(E, G) = 4 + 5 - 2 \max(|\uparrow B|, |\uparrow D|) = 5$$

$$d_l(E, G) = 2 + 2 - 2 \cdot 1 = 2$$

DISTANCE DISCREPANCY

Normalized Distance:

$$\bar{d}_u(a, b) := \frac{d_u(a, b)}{|P| - 1} \in [0, 1], \quad \bar{d}_l(a, b) := \frac{d_l(a, b)}{|P| - 1} \in [0, 1].$$

Distance Discrepancy: Relative distance between $a, b \in P$ should be the same as $a', b' \in P'$:

$$D_{F,d} := \frac{\sum_{\vec{f}, \vec{g} \in F} |\bar{d}(a, b) - \bar{d}'(a', b')|}{{|F| \choose 2}}$$

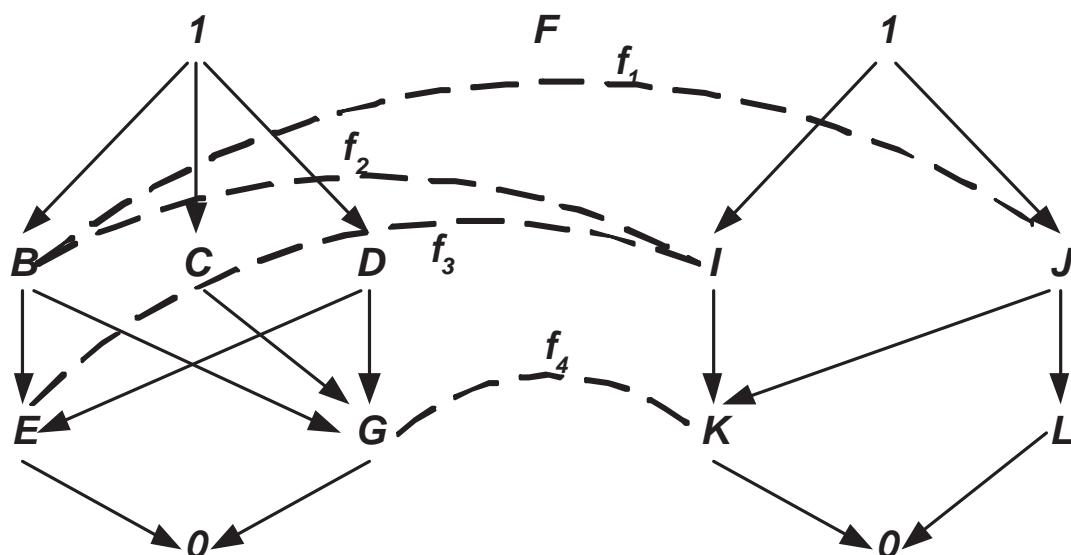

Upper Vs. Lower Distance: Lower distance preferable for top-bounded, downward-branching structures, especially if lacking multiple inheritance

EXAMPLE

	$\vec{f}_1 = \langle B, J \rangle$	$\vec{f}_2 = \langle B, I \rangle$	$\vec{f}_3 = \langle E, I \rangle$	$\vec{f}_4 = \langle G, K \rangle$
$\vec{f}_1 = \langle B, J \rangle$	0.00	0.60	0.27	0.07
$\vec{f}_2 = \langle B, I \rangle$	0.60	0.00	0.33	0.13
$\vec{f}_3 = \langle E, I \rangle$	0.27	0.33	0.00	0.13
$\vec{f}_4 = \langle G, K \rangle$	0.07	0.13	0.13	0.00

$$D(F) = \frac{0.6 + 0.27 + 0.07 + 0.33 + 0.13 + 0.13 + 1.53}{6} = .255$$

RELATION TO SEMANTIC SIMILARITIES

Compare to $d_l(a, b) = |\downarrow a| + |\downarrow b| - 2 \max_{c \in a \wedge b} |\downarrow c|$

Poset $\mathcal{P} = \langle P, \leq \rangle$, probability distribution

$p: P \mapsto [0, 1], \sum_{a \in P} p(a) = 1$, “cumulative” $\beta(a) := \sum_{b \leq a} p(b)$

Resnik: $\delta(a, b) = \max_{c \in a \vee b} [-\log_2(\beta(c))]$

Lin:

$$\delta(a, b) = \frac{2 \max_{c \in a \vee b} [\log_2(\beta(c))]}{\log_2(\beta(a)) + \log_2(\beta(b))}$$

Jiang and Conrath:

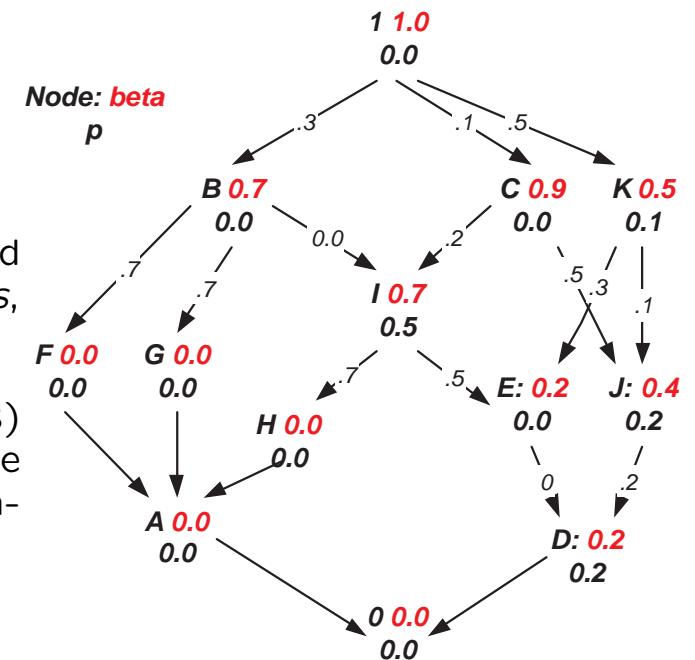

$$\delta(a, b) = 2 \max_{c \in a \vee b} [\log_2(\beta(c))] - \log_2(\beta(a)) - \log_2(\beta(b))$$

Issues:

- General mathematical grounding
- Not *rely* on probabilistic weighting

A Butanitsky and G Hirst: (2006) “Evaluating WordNet-based measures of semantic distance.” *Computational Linguistics*, 32(1), 13–47.

Lord, PW; Stevens, Robert; Brass, A; and Goble, C: (2003) “Investigating Semantic Similarity Measures Across the Gene Ontology: the Relationship Between Sequence and Annotation”, *Bioinformatics*, v. 10, pp. 1275-1283

GROUNDING IN ORDER METRICS

- Semimodular functions on finite, bounded orders $\langle P, \leq \rangle$
- E.g. generalized Kolmogorov probabilities, information measures in graphical models (Studeny 2005)

Generalized Join, Meet: $a \nabla b := \uparrow a \cap \uparrow b$, $a \Delta b := \downarrow a \cap \downarrow b$

Isotone Map: $v: P \mapsto \mathbb{R}, a \leq b \rightarrow v(a) \leq v(b)$

$$v^\nabla(a, b) := \min_{c \in a \nabla b} v(c), \quad v_\Delta(a, b) := \max_{c \in a \Delta b} v(c)$$

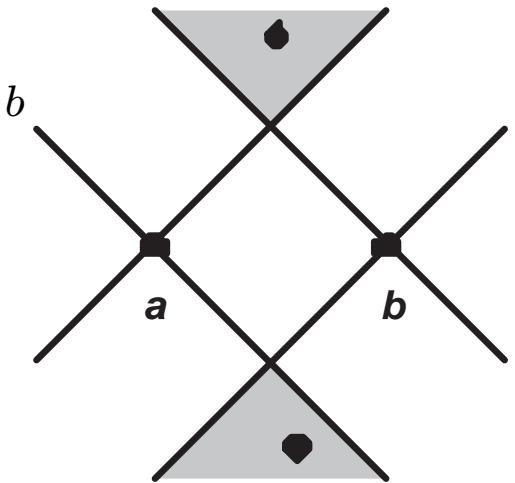

Antitone Map: $v: P \mapsto \mathbb{R}, a \leq b \rightarrow v(a) \geq v(b)$

$$v^\nabla(a, b) := \max_{c \in a \nabla b} v(c), \quad v_\Delta(a, b) := \min_{c \in a \Delta b} v(c)$$

Valuations: Super- and sub-modularity:

Lower: $v(a) + v(b) \leq v^\nabla(a, b) + v_\Delta(a, b)$

Upper: $v(a) + v(b) \geq v^\nabla(a, b) + v_\Delta(a, b)$

Metric $d(a, b)$	Lower Valuation $v(a) + v(b) \leq v^\nabla(a, b) + v_\Delta(a, b)$	Upper Valuation $v(a) + v(b) \geq v^\nabla(a, b) + v_\Delta(a, b)$
Isotone	$v(a) + v(b) - 2v_\Delta(a, b)$	$2v^\nabla(a, b) - v(a) - v(b)$
Antitone	$v(a) + v(b) - 2v^\nabla(a, b)$	$2v_\Delta(a, b) - v(a) - v(b)$
