Learning graphical models

Parameter estimation

- We assume the structure of the model is given
- We are given a dataset of examples $\mathcal{D} = {\mathbf{x}(1), \dots, \mathbf{x}(N)}$
- Each example $\mathbf{x}(i)$ is a configuration for *all* (complete data) or *some* (incomplete data) variables in the model
- We need to estimate the parameters of the model (conditional probability distributions) from the data
- The simplest approach consists of learning the parameters maximizing the *likelihood* of the data:

$$\boldsymbol{\theta}^{\max} = \operatorname{argmax}_{\boldsymbol{\theta}} p(\mathcal{D}|\boldsymbol{\theta}) = \operatorname{argmax}_{\boldsymbol{\theta}} \mathcal{L}(\mathcal{D}, \boldsymbol{\theta})$$

Learning Bayesian Networks

Maximum likelihood estimation, complete data

$$\begin{split} p(\mathcal{D}|\boldsymbol{\theta}) &= \prod_{i=1}^N p(\mathbf{x}(i)|\boldsymbol{\theta}) \\ &= \prod_{i=1}^N \prod_{j=1}^m p(\mathbf{x}_j(i)| \mathrm{pa}_j(i), \boldsymbol{\theta}) \end{split}$$

examples independent given $\boldsymbol{\theta}$

factorization for BN

Learning Bayesian Networks

Maximum likelihood estimation, complete data

$$\begin{split} p(\mathcal{D}|\boldsymbol{\theta}) &= \prod_{i=1}^{N} \prod_{j=1}^{m} p(\mathbf{x}_{j}(i)|\mathbf{pa}_{j}(i), \boldsymbol{\theta}) & \text{factorization for BN} \\ &= \prod_{i=1}^{N} \prod_{j=1}^{m} p(\mathbf{x}_{j}(i)|\mathbf{pa}_{j}(i), \boldsymbol{\theta}_{X_{j}|\mathbf{pa}_{j}}) & \text{disjoint CPD parameters} \end{split}$$

Learning graphical models

Maximum likelihood estimation, complete data

• The parameters of each CPD can be estimated independently:

$$\boldsymbol{\theta}_{X_{j}|\mathbf{P}\mathbf{a}_{j}}^{\max} = \operatorname{argmax}_{\boldsymbol{\theta}_{X_{j}|\mathbf{P}\mathbf{a}_{j}}} \underbrace{\prod_{i=1}^{N} p(\mathbf{x}_{j}(i)|\mathbf{p}\mathbf{a}_{j}(i), \boldsymbol{\theta}_{X_{j}|\mathbf{P}\mathbf{a}_{j}})}_{\mathcal{L}(\boldsymbol{\theta}_{X_{j}|\mathbf{P}\mathbf{a}_{j}}, \mathcal{D})}$$

- A discrete CPD P(X|U), can be represented as a table, with:
 - a number of rows equal to the number Val(X) of configurations for X
 - a number of columns equal to the number Val(U) of configurations for its parents U
 - each table entry $\theta_{x|\mathbf{u}}$ indicating the probability of a specific configuration of X = x and its parents $U = \mathbf{u}$

Learning graphical models

Maximum likelihood estimation, complete data

• Replacing p(x(i)|pa(i)) with $\theta_{x(i)|u(i)}$, the local likelihood of a single CPD becames:

$$\begin{split} \mathcal{L}(\boldsymbol{\theta}_{X|\mathrm{Pa}}, \mathcal{D}) &= \prod_{i=1}^{N} p(x(i)|\mathrm{pa}(i), \boldsymbol{\theta}_{X|\mathrm{Pa}_{j}}) \\ &= \prod_{i=1}^{N} \theta_{x(i)|\mathbf{u}(i)} \\ &= \prod_{\mathbf{u} \in Val(\boldsymbol{U})} \left[\prod_{x \in Val(X)} \theta_{x|\mathbf{u}}^{N_{\mathbf{u},x}} \right] \end{split}$$

where $N_{\mathbf{u},x}$ is the number of times the specific configuration $X = x, \mathbf{U} = \mathbf{u}$ was found in the data

Learning graphical models

Maximum likelihood estimation, complete data

- A column in the CPD table contains a multinomial distribution over values of X for a certain configuration of the parents U
- Thus each column should sum to one: $\sum_{x} \theta_{x|\mathbf{u}} = 1$
- Parameters of different columns can be estimated independently
- For each multinomial distribution, zeroing the gradient of the maximum likelihood and considering the normalization constraint, we obtain:

$$\theta_{x|\mathbf{u}}^{max} = \frac{N_{\mathbf{u},x}}{\sum_{x} N_{\mathbf{u},x}}$$

• The maximum likelihood parameters are simply the fraction of times in which the specific configuration was observed in the data

Learning graphical models

Adding priors

- ML estimation tends to overfit the training set
- · Configuration not appearing in the training set will receive zero probability
- A common approach consists of combining ML with a prior probability on the parameters, achieving a maximuma-posteriori estimate:

$$\boldsymbol{\theta}^{\max} = \operatorname{argmax}_{\boldsymbol{\theta}} p(\mathcal{D}|\boldsymbol{\theta}) p(\boldsymbol{\theta})$$

Learning graphical models

Dirichlet priors

- The conjugate (read natural) prior for a multinomial distribution is a Dirichlet distribution with parameters $\alpha_{x|u}$ for each possible value of x
- The resulting maximum-a-posteriori estimate is:

$$\theta_{x|\mathbf{u}}^{max} = \frac{N_{\mathbf{u},x} + \alpha_{x|\mathbf{u}}}{\sum_{x} \left(N_{\mathbf{u},x} + \alpha_{x|\mathbf{u}} \right)}$$

• The prior is like having observed $\alpha_{x|\mathbf{u}}$ imaginary samples with configuration $X = x, U = \mathbf{u}$

Learning graphical models

Incomplete data

- With incomplete data, some of the examples miss evidence on some of the variables
- Counts of occurrences of different configurations cannot be computed if not all data are observed
- The full Bayesian approach of integrating over missing variables is often intractable in practice
- We need approximate methods to deal with the problem

Learning with missing data: Expectation-Maximization

E-M for Bayesian nets in a nutshell

- Sufficient statistics (counts) cannot be computed (missing data)
- Fill-in missing data inferring them using current parameters (solve inference problem to get *expected* counts)
- · Compute parameters maximizing likelihood (or posterior) of such expected counts
- · Iterate the procedure to improve quality of parameters

Learning with missing data: Expectation-Maximization

Expectation-Maximization algorithm

e-step Compute the expected sufficient statistics for the complete dataset, with expectation taken wrt the joint distribution for X conditioned of the current value of θ and the known data D:

$$\mathbf{E}_{p(\boldsymbol{x}|\mathcal{D},\boldsymbol{\theta})}[N_{ijk}] = \sum_{l=1}^{n} p(X_i(l) = x_k, \mathbf{Pa}_i(l) = \mathbf{pa}_j | \boldsymbol{X}_l, \boldsymbol{\theta})$$

- If $X_i(l)$ and $Pa_i(l)$ are observed for X_l , it is either zero or one
- · Otherwise, run Bayesian inference to compute probabilities from observed variables

Learning with missing data: Expectation-Maximization Expectation-Maximization algorithm

m-step compute parameters maximizing likelihood of the complete dataset D_c (using expected counts):

$$\boldsymbol{\theta}^* = \operatorname{argmax}_{\boldsymbol{\theta}} p(D_c | \boldsymbol{\theta})$$

which for each multinomial parameter evaluates to:

$$\theta_{ijk}^* = \frac{\mathrm{E}_{p(\boldsymbol{x}|\mathcal{D},\boldsymbol{\theta})}[N_{ijk}]}{\sum_{k=1}^{r_i} \mathrm{E}_{p(\boldsymbol{x}|\mathcal{D},\boldsymbol{\theta})}[N_{ijk}]}$$

Note

ML estimation can be replaced by maximum a-posteriori (MAP) estimation giving:

$$\theta_{ijk}^* = \frac{\alpha_{ijk} + \mathbf{E}_{p(\boldsymbol{x}|\mathcal{D},\boldsymbol{\theta},S)}[N_{ijk}]}{\sum_{k=1}^{r_i} \left(\alpha_{ijk} + \mathbf{E}_{p(\boldsymbol{x}|\mathcal{D},\boldsymbol{\theta},S)}[N_{ijk}] \right)}$$

Learning structure of graphical models

Approaches

constraint-based test conditional independencies on the data and construct a model satisfying them

- score-based assign a score to each possible structure, define a search procedure looking for the structure maximizing the score
- **model-averaging** assign a prior probability to each structure, and average prediction over all possible structures weighted by their probabilities (full Bayesian, intractable)

Appendix: Learning the structure Bayesian approach

- Let S be the space of possible structures (DAGS) for the domain X.
- Let \mathcal{D} be a dataset of observations
- Predictions for a new instance are computed marginalizing over both structures and parameters:

$$p(\boldsymbol{X}_{N+1}|\mathcal{D}) = \sum_{S \in \mathcal{S}} \int_{\boldsymbol{\theta}} P(\boldsymbol{X}_{N+1}, S, \boldsymbol{\theta}|\mathcal{D}) d\boldsymbol{\theta}$$

$$= \sum_{S \in \mathcal{S}} \int_{\boldsymbol{\theta}} P(\boldsymbol{X}_{N+1}|S, \boldsymbol{\theta}, \mathcal{D}) P(S, \boldsymbol{\theta}|\mathcal{D}) d\boldsymbol{\theta}$$

$$= \sum_{S \in \mathcal{S}} \int_{\boldsymbol{\theta}} P(\boldsymbol{X}_{N+1}|S, \boldsymbol{\theta}) P(\boldsymbol{\theta}|S, \mathcal{D}) P(S|\mathcal{D}) d\boldsymbol{\theta}$$

$$= \sum_{S \in \mathcal{S}} P(S|\mathcal{D}) \int_{\boldsymbol{\theta}} P(\boldsymbol{X}_{N+1}|S, \boldsymbol{\theta}) P(\boldsymbol{\theta}|S, \mathcal{D}) d\boldsymbol{\theta}$$

Learning the structure

Problem

Averaging over all possible structures is too expensive

Model selection

- Choose a *best* structure S^* and assume $P(S^*|\mathcal{D}) = 1$
- Approaches:
 - Score-based:
 - * Assign a score to each structure
 - \ast Choose S^{\ast} to maximize the score
 - Constraint-based:
 - * Test conditional independencies on data
 - * Choose S^* that satisfies these independencies

Score-based model selection

Structure scores

• Maximum-likelihood score:

$$S^* = argmax_{S \in \mathcal{S}} p(\mathcal{D}|S)$$

• Maximum-a-posteriori score:

$$S^* = argmax_{S \in \mathcal{S}} p(\mathcal{D}|S) p(S)$$

Computing $P(\mathcal{D}|S)$

Maximum likelihood approximation

• The easiest solution is to approximate $P(\mathcal{D}|S)$ with the maximum-likelihood score over the parameters:

$$P(\mathcal{D}|S) \approx max_{\theta} P(\mathcal{D}|S,\theta)$$

- Unfortunately, this boils down to adding a connection between two variables if their empirical mutual information over the training set is non-zero (proof omitted)
- Because of noise, empirical mutual information between any two variables is almost never exactly zero ⇒ fully connected network

Computing $P(\mathcal{D}|S) \equiv P_S(\mathcal{D})$: Bayesian-Dirichlet scoring

Simple case: setting

- X is a single variable with r possible realizations (r-faced die)
- S is a single node
- Probability distribution is a multinomial with Dirichlet priors $\alpha_1, \ldots, \alpha_r$.
- \mathcal{D} is a sequence of N realizations (die tosses)

Computing $P_S(\mathcal{D})$: Bayesian-Dirichlet scoring

Simple case: approach

• Sort \mathcal{D} according to outcome:

$$\mathcal{D} = \{x^1, x^1, \dots, x^1, x^2, \dots, x^2, \dots, x^r, \dots, x^r\}$$

• Its probability can be decomposed as:

$$P_S(\mathcal{D}) = \prod_{t=1}^N P_S(X(t)|\underbrace{X(t-1),\ldots,X(1)}_{\mathcal{D}(t-1)})$$

• The prediction for a new event given the past is:

$$P_S(X(t+1) = x^k | \mathcal{D}(t)) = \mathbb{E}_{p_S(\boldsymbol{\theta} | \mathcal{D}(t))}[\boldsymbol{\theta}_k] = \frac{\alpha_k + N_k(t)}{\alpha + t}$$

where $N_k(t)$ is the number of times we have $X = x^k$ in the first t examples in \mathcal{D}

Computing $P_S(\mathcal{D})$: Bayesian-Dirichlet scoring

Simple case: approach

$$P_{S}(\mathcal{D}) = \frac{\alpha_{1}}{\alpha} \frac{\alpha_{1}+1}{\alpha+1} \cdots \frac{\alpha_{1}+N_{1}-1}{\alpha+N_{1}-1}$$
$$\cdot \frac{\alpha_{2}}{\alpha+N_{1}} \frac{\alpha_{2}+1}{\alpha+N_{1}+1} \cdots \frac{\alpha_{2}+N_{2}-1}{\alpha+N_{1}+N_{2}-1} \cdots$$
$$\cdot \frac{\alpha_{r}}{\alpha+N_{1}+\cdots+N_{r-1}} \cdots \frac{\alpha_{r}+N_{r}-1}{\alpha+N-1}$$
$$= \frac{\Gamma(\alpha)}{\Gamma(\alpha+N)} \prod_{k=1}^{r} \frac{\Gamma(\alpha_{k}+N_{k})}{\alpha_{k}}$$

where we used the Gamma function $(\Gamma(x + 1) = x\Gamma(x))$:

$$\alpha(1+\alpha)\dots(N-1+\alpha) = \frac{\Gamma(N+\alpha)}{\Gamma(\alpha)}$$

Computing $P_S(\mathcal{D})$: Bayesian-Dirichlet scoring

General case

$$P_S(\mathcal{D}) = \prod_i \prod_j \frac{\Gamma(\alpha_{ij})}{\Gamma(\alpha_{ij} + N_{ij})} \prod_{k=1}^r \frac{\Gamma(\alpha_{ijk} + N_{ijk})}{\alpha_{ijk}}$$

where

- $i \in \{1, \ldots, n\}$ ranges over nodes in the network
- $j \in \{1, q_i\}$ ranges over configurations of X_i 's parents
- $k \in \{1, r_i\}$ ranges over states of X_i

Note

The score is **decomposable**: it is the product of independent scores associated with the distribution of each node in the net

Search strategy

Approach

- Discrete search problem: NP-hard for nets whose nodes have at most k > 1 parents.
- Heuristic search strategies employed:
 - Search space: set of DAGs
 - Operators: add, remove, reverse one arc
 - Initial structure: e.g. random, fully disconnected, ...
 - Strategies: hill climbing, best first, simulated annealing

Note

Decomposable scores allow to recompute local scores only for a single move
