# History of nuXmv

---

## SMV

Symbolic Model Verifier developed by McMillan in 1993.

## NuSMV

Open-source symbolic model checker for SMV models. It has been developed by FBK, Carnegie Mellon University, University of Genoa and University of Trento.

## nuXmv

Extends NuSMV for infinite state and timed (since v2) systems. Binary available for non-commercial or academic purposes only. Developed and maintained by the Embedded Systems unit of FBK.

# Application of nuXvm

---

- ▶ nuXmv allows for the verification of:
  - ▶ *finite-state systems* through SAT and BDD based algorithms;
  - ▶ *infinite-state systems* (e.g. systems with *real* and *integer* variables) through SMT-based techniques running on top of **MathSAT5**;
  - ▶ *timed systems* (e.g. allows *clock* type) via reduction to infinite state model checking.
- ▶ nuXmv supports *synchronous* systems;
- ▶ *asynchronous* systems are no longer supported!

# Outline

---

1. Introduction
2. nuXmv interactive shell
3. nuXmv Modeling
4. Modules
5. Homework

# Interactive shell [1/3]

---

- ▶ `nuXmv -int` (or `NuSMV -int`) activates an interactive shell
- ▶ `help` shows the list of all commands (if a command name is given as argument, detailed information for that command will be provided).  
**note: option `-h` prints the command line help for each command.**
- ▶ `reset` resets the whole system (in order to read in another model and to perform verification on it).
- ▶ `read_model [-i filename]` sets the input model and reads it.
- ▶ `go`, `go_bmc`, `go_msat` initialize `nuXmv` for verification or simulation with a specific backend engine.

# Interactive shell [2/3]

---

- ▶ `pick_state [-v] [-a] [-r | -i]` picks a state from the set of initial states.
  - ▶ `-v` prints the chosen state.
  - ▶ `-r` picks a state from the set of the initial states randomly.
  - ▶ `-i` picks a state from the set of the initial states interactively.
  - ▶ `-a` displays all state variables (requires `-i`).
- ▶ `simulate [-p | -v] [-a] [-r | -i] -k N` generates a sequence of at most `N` transitions starting from the current state.
  - ▶ `-p` prints the changing variables in the generated trace;
  - ▶ `-v` prints changed and unchanged variables in the generated trace;
  - ▶ `-a` prints all state variables (requires `-i`);
  - ▶ `-r` at every step picks the next state randomly.
  - ▶ `-i` at every step picks the next state interactively.
- ▶ `print_current_state [-h] [-v]` prints out the current state.
  - ▶ `-v` prints all the variables.

# Interacting Shell [2/3] - Output Example

```
nuXmv > reset
nuXmv > read_model -i example01.smv ; go
nuXmv > pick_state -v; simulate -v
Trace Description: Simulation Trace
Trace Type: Simulation
-> State: 1.1 <-
    b0 = FALSE
***** Simulation Starting From State 1.1 *****
Trace Description: Simulation Trace
Trace Type: Simulation
-> State: 1.1 <-
    b0 = FALSE
-> State: 1.2 <-
    b0 = TRUE
-> State: 1.3 <-
    b0 = FALSE
-> State: 1.4 <-
    b0 = TRUE
-> State: 1.5 <-
    b0 = FALSE
-> State: 1.6 <-
    b0 = TRUE
...

```

# Interacting Shell [3/3]

---

- ▶ `show_vars [-s] [-f] [-i] [-t] [-v]` prints the variables content and type
  - ▶ `-s` print state variables;
  - ▶ `-f` print frozen variables;
  - ▶ `-i` print input variables;
  - ▶ `-t` prints the number of variables;
  - ▶ `-v` prints verbosely;
- ▶ `quit` stops the program.

# Outline

---

1. Introduction
2. nuXmv interactive shell
3. nuXmv Modeling
  - Basic Types
  - Expressions
  - Transition Relation
  - Miscellany
  - Constraint Style Modeling
4. Modules
5. Homework

# First SMV model

- ▶ an SMV model is composed by a number of **modules**;
- ▶ each **module** can contain:
  - ▶ state variable declarations;
  - ▶ formulae defining the valid *initial states*;
  - ▶ formulae defining the *transition relation*;

## Example:

```

MODULE main
VAR
    b0 : boolean;

ASSIGN
    init(b0) := FALSE;
    next(b0) := !b0;
    
```

# Basic Types [1/3]

---

**boolean:** TRUE, FALSE, ...

```
x : boolean;
```

**enumerative:**

```
s : {ready, busy, waiting, stopped};
```

**bounded integers\*** (intervals):

```
n : 1..8;
```

\*: integer numbers must be within C/C++ INT\_MIN and INT\_MAX bounds

# Basic Types [2/3]

---

**integers\***: -1, 0, 1, ...

n : integer;

**rationals**: 1.66, f'2/3, 2e3, 10e-1, ...

r : real;

**words**: used to model arrays of bits supporting bitwise logical and arithmetic operations.

- ▶ unsigned word[3];
- ▶ signed word[7];

\*: integer numbers must be within C/C++ INT\_MIN and INT\_MAX bounds

# Basic Types [3/3]

---

## arrays:

declared with a couple of lower/upper bounds for the index and a type

### VAR

```
-- array of 11 elements  
x : array 0..10 of boolean;  
-- array of 3 elements  
y : array -1..1 of {red, green, orange};  
-- array of array  
z : array 1..10 of array 1..5 of boolean;
```

### ASSIGN

```
init(x[5]) := bool(1);  
-- any value in the set  
init(y[0]) := {red, green};  
init(z[3][2]) := TRUE;
```

Array indexes *must be constants*;

# Adding a state variable

```

MODULE main
VAR
    b0 : boolean;
    b1 : boolean;

ASSIGN
    init(b0) := FALSE;
    next(b0) := !b0;
    
```

Remarks:

- ▶ the FSM is the result of the **synchronous** composition of the “subsystems” for b0 and b1
- ▶ the new state space is the cartesian product of the ranges of the variables.

# Initial States [1/2]

---

## Example:

```
init(x) := FALSE;      -- x must be FALSE
init(y) := {1, 2, 3}; -- y can be either 1, 2 or 3
```

```
init(<variable>) := <simple_expression>;
```

- ▶ constrains the **initial value** of <variable> to satisfy the <simple\_expression>;
- ▶ the **initial** value of an **unconstrained** variable can be any of those allowed by its domain;

## set of initial states

is given by the set of states whose variables satisfy **all** the `init()` **constraints** in a module.

# Initial States [2/2]

Example:

```

MODULE main
  VAR
    b0 : boolean;
    b1 : boolean;

  ASSIGN
    init(b0) := FALSE;
    next(b0) := !b0;

    init(b1) := FALSE;
  
```

# Expressions [1/3]

---

- ▶ arithmetic operators:

+      -      \*      /      mod      - (unary)

- ▶ comparison operators:

=      !=      >      <      <=      >=

- ▶ logic operators:

&      |      xor      ! (not)      ->      <->

- ▶ bitwise operators:

«      »

- ▶ set operators: {v1, v2, ..., vn}

- ▶ in: tests a value for membership in a set (*set inclusion*)
- ▶ union: takes the union of 2 sets (*set union*)

- ▶ count operator: counts number of true *boolean* expressions  
count(b1, b2, ..., bn)

# Expressions [2/3]

- ▶ case expression:

```
case
  c1   : e1;
  c2   : e2;
  ...
  TRUE : en;
esac
```

C/C++ equivalent:

```
if (c1) then e1;
else if (c2) then e2;
...
else en;
```

- ▶ if-then-else expression:

```
cond_expr ? basic_expr1 : basic_expr2
```

- ▶ conversion operators: `toint`, `bool`, `floor`, and
  - ▶ `swconst`, `uwconst`: convert an integer to a signed and an unsigned word respectively.
  - ▶ `word1` converts boolean to a single word bit.
  - ▶ `unsigned` and `signed` convert signed word to unsigned word and vice-versa.

# Expressions [3/3]

---

- ▶ expressions in SMV do not necessarily evaluate to one value. In general, they can represent a set of possible values.

```
init(var) := {a,b,c} union {x,y,z};
```

- ▶ The meaning of `:=` in assignments is that the lhs can **non-deterministically** be assigned to any value in the set of values represented by the rhs.
- ▶ A constant `c` is considered as a syntactic abbreviation for `{c}` (the singleton containing `c`).

# Transition Relation [1/2]

## Transition Relation

specifies a constraint on the values that a variable can assume in the *next state*, given the value of variables in the *current state*.

$\text{next}(\langle \text{variable} \rangle) := \langle \text{next\_expression} \rangle;$

- ▶  $\langle \text{next\_expression} \rangle$  can depend both on “current” and “next” variables:

$\text{next}(a) := \{ a, a+1 \};$

$\text{next}(b) := b + (\text{next}(a) - a);$

- ▶  $\langle \text{next\_expression} \rangle$  must evaluate to values in the domain of  $\langle \text{variable} \rangle;$
- ▶ the **next** value of an **unconstrained** variable evolves **non-deterministically**;

# Transition Relation [2/2]

Example:

modulo-4 counter

```
MODULE main
```

```
VAR
```

```
  b0 : boolean;
```

```
  b1 : boolean;
```

```
ASSIGN
```

```
  init(b0) := FALSE;
```

```
  next(b0) := !b0;
```

```
  init(b1) := FALSE;
```

```
  next(b1) := case
```

```
    b0 : !b1;
```

```
    TRUE : b1;
```

```
  esac;
```

# Output Variable [1/2]

---

## output variable

A variable whose value deterministically depends on the value of other “current” state variables and for which no `init()` or `next()` are defined.

```
<variable> := <simple_expression>;
```

- ▶ `<simple_expression>` must evaluate to values in the domain of the `<variable>`.
- ▶ used to model *outputs* of a system;

# Output Variable [2/2]

## Example:

```
MODULE main
```

```
VAR
```

```
  b0 : boolean;
  b1 : boolean;
  out : 0..3;
```

```
ASSIGN
```

```
  init(b0) := FALSE;
  next(b0) := !b0;
```

```
  init(b1) := FALSE;
  next(b1) := ((!b0 & b1) | (b0 & !b1));
```

```
  out := toint(b0) + 2*toint(b1);
```

# Assignment Rules ( $:=$ )

---

- ▶ **single assignment rule** – each variable may be assigned only once; **Illegal** examples:

<code>init(var) := ready;</code>	<code>var := ready;</code>	<code>next(var) := ready;</code>
<code>init(var) := busy;</code>	<code>var := busy;</code>	<code>var := busy;</code>
<hr/>		
<code>next(var) := ready;</code>	<code>init(var) := ready;</code>	
<code>next(var) := busy;</code>	<code>var := busy;</code>	

# Assignment Rules ( $:=$ )

- ▶ **single assignment rule** – each variable may be assigned only once; **Illegal** examples:

<code>init(var) := ready;</code>	<code>var := ready;</code>	<code>next(var) := ready;</code>
<code>init(var) := busy;</code>	<code>var := busy;</code>	<code>var := busy;</code>
<hr/>		
<code>next(var) := ready;</code>	<code>init(var) := ready;</code>	
<code>next(var) := busy;</code>	<code>var := busy;</code>	

- ▶ **circular dependency rule** – a set of equations must not have “cycles” in its dependency graph, unless broken by delays;

**Illegal** examples:

<code>next(x) := next(y);</code>	<code>x := (x + 1) mod 2;</code>	<code>next(x) := x &amp; next(x);</code>
<code>next(y) := next(x);</code>		

**Legal** example:

<code>next(x) := next(y);</code>
<code>next(y) := y &amp; x;</code>

# DEFINE declarations

---

DEFINE <id> := <simple\_expression>;

- ▶ similar to *C/C++ macro* definitions: each occurrence of the defined symbol is replaced with the body of the definition
- ▶ provide an alternative way of defining *output variables*;

## Example:

```
MODULE main
  VAR
    b0 : boolean;
    b1 : boolean;
  ASSIGN
    init(b0) := FALSE;
    next(b0) := !b0;
    init(b1) := FALSE;
    next(b1) := ((!b0 & b1) | (b0 & !b1));
  DEFINE
    out := toint(b0) + 2*toint(b1);
```

# Example: modulo 4 counter with reset

The counter can be reset by an external “uncontrollable” signal.

```
MODULE main
VAR
  b0 : boolean; b1 : boolean; reset : boolean;
ASSIGN
  init(b0) := FALSE;
  init(b1) := FALSE;
  next(b0) := case
    reset = TRUE   : FALSE;
    reset = FALSE  : !b0;
  esac;
  next(b1) := case
    reset : FALSE;
    TRUE  : ((!b0 & b1) | (b0 & !b1));
  esac;
DEFINE
  out := toint(b0) + 2*toint(b1);
```

DEFINE

# Exercise 1

---

## Exercise:

simulate the system with nuXmv and draw the FSM.

```
MODULE main
VAR
  request : boolean;
  state   : { ready, busy };

ASSIGN
  init(state) := ready;
  next(state) :=
    case
      state = ready & request : busy;
    TRUE                       : { ready, busy };
  esac;
```

# Exercise 1

## Exercise:

simulate the system with nuXmv and draw the FSM.

```

MODULE main
VAR
    request : boolean;
    state   : { ready, busy };

ASSIGN
    init(state) := ready;
    next(state) :=
        case
            state = ready & request : busy;
            TRUE                     : { ready, busy };
        esac;
    
```

# Constraint Style Modeling [1/4]

---

```
MODULE main
VAR
request : boolean; state : {ready,busy};
ASSIGN
  init(state) := ready;
  next(state) := case
    state = ready & request : busy;
    TRUE                    : {ready,busy};
  esac;
```

Every program can be alternatively defined in a *constraint style*:

```
MODULE main
VAR
  request : boolean; state : {ready,busy};
INIT
  state = ready
TRANS
  (state = ready & request) -> next(state) = busy
```

# Constraint Style Modeling [2/4]

- ▶ a model can be specified by zero or more constraints on:
  - ▶ *initial states*:  
INIT <simple\_expression>
  - ▶ *transitions*:  
TRANS <next\_expression>
  - ▶ *invariant states*:  
INVAR <simple\_expression>
- ▶ constraints can be mixed with assignments;
- ▶ any propositional formula is allowed as constraint;
- ▶ not all **constraints** can be easily rewritten in terms of assignments!

TRANS

$$\text{next}(b0) + 2*\text{next}(b1) + 4*\text{next}(b2) = \\ (b0 + 2*b1 + 4*b2 + \text{tick}) \bmod 8$$

## assignment style

- :
- ▶ by construction, there is always *at least one initial state*;
  - ▶ by construction, all states have *at least one next state*;
  - ▶ *non-determinism is apparent* (unassigned variables, set assignments...).

# Constraint Style Modeling [4/4]

## constraint style

- ▶ INIT constraints *can be inconsistent*  $\implies$  no initial state!
  - ▶ any specification (also SPEC 0) is vacuously true.
- ▶ TRANS constraints *can be inconsistent*:  $\implies$  deadlock state!

### Example:

```
MODULE main
VAR b : boolean;
TRANS b -> FALSE;
```

- ▶ **tip:** use `check_fsm` to detect deadlock states
- ▶ *non-determinism is hidden:*

```
TRANS (state = ready & request) -> next(state) = busy
```

# Example: Constraint Style & Case

```
MODULE main()
```

```
VAR
```

```
state : {S0, S1, S2};
```

```
DEFINE
```

```
go_s1 := state != S2;
```

```
go_s2 := state != S1;
```

```
INIT
```

```
state = S0;
```

```
TRANS
```

```
case
```

```
go_s1 : next(state) = S1;
```

```
go_s2 : next(state) = S2;
```

```
esac;
```

► Q: does it correspond to the FSM?

```

MODULE main()
VAR
  state : {S0, S1, S2};

DEFINE
  go_s1 := state != S2;
  go_s2 := state != S1;

INIT
  state = S0;

TRANS
case
  go_s1 : next(state) = S1;
  go_s2 : next(state) = S2;
esac;
    
```

- ▶ **Q: does it correspond to the FSM?** No: cases are evaluated in order!

# Example: Constraint Style & Swap

```

MODULE main()
VAR
  arr: array 0..1 of {1,2};
  i  : 0..1;

```

```

ASSIGN
  init(arr[0]) := 1;
  init(arr[1]) := 2;

  init(i) := 0;
  next(i) := 1-i;

```

```

TRANS
  next(arr[i]) = arr[1-i] &
  next(arr[1-i]) = arr[i];

```

► Q: does it correspond to the FSM?

```

MODULE main()
VAR
  arr: array 0..1 of {1,2};
  i  : 0..1;
    
```

ASSIGN

```

  init(arr[0]) := 1;
  init(arr[1]) := 2;
    
```

```

  init(i) := 0;
  next(i) := 1-i;
    
```

TRANS

```

  next(arr[i]) = arr[1-i] &
  next(arr[1-i]) = arr[i];
    
```

- ▶ **Q: does it correspond to the FSM?** No: everything inside the **next()** operator is evaluated within the next state, indexes included!

# Outline

---

1. Introduction
2. nuXmv interactive shell
3. nuXmv Modeling
4. Modules
  - Modules Definition
  - Modules Composition
5. Homework

# Modules [1/3]

SMV program = main module + 0 or *more* other modules

- ▶ a module can be **instantiated** as a VAR in other modules
- ▶ dot notation for accessing variables that are **local** to a module instance (e.g., m1.out, m2.out).

## Example:

```

MODULE counter
  VAR out: 0..9;
  ASSIGN next(out) :=
      (out + 1) mod 10;

MODULE main
  VAR m1 : counter; m2 : counter;
      sum: 0..18;
  ASSIGN sum := m1.out + m2.out;
    
```

# Modules [2/3]

A module declaration can be *parametric*:

- ▶ a parameter is passed by reference;
- ▶ any expression can be used as parameter;

Example:

```

MODULE counter(in)
  VAR out: 0..9;
  ...
MODULE main
  VAR m1 : counter(m2.out);
      m2 : counter(m1.out);
  ...
    
```

# Modules [3/3]

---

- ▶ modules can be **composed**
- ▶ modules *without parameters and assignments* can be seen as simple **records**

## Example:

```
MODULE point
VAR
  x: -10..10;
  y: -10..10;
```

```
MODULE circle
VAR
  center: point;
  radius: 0..10;
```

```
MODULE main
VAR c: circle;
ASSIGN
  init(c.center.x) := 0;
  init(c.center.y) := 0;
  init(c.radius)   := 5;
```

# Synchronous composition [1/2]

The composition of modules is **synchronous** by default:  
*all modules move at each step.*

```

MODULE cell(input)
VAR
  val : {red, green, blue};
ASSIGN
  next(val) := input;

MODULE main
VAR
  c1 : cell(c3.val);
  c2 : cell(c1.val);
  c3 : cell(c2.val);
    
```

# Synchronous composition [2/2]

---

A possible execution:

<i>step</i>	<i>c1.val</i>	<i>c2.val</i>	<i>c3.val</i>
0	red	green	blue
1	blue	red	green
2	green	blue	red
3	red	green	blue
4	...	...	...
5	red	green	blue

# Exercise: Adder [1/3]

## Exercise 7.1: implementing adder

Implement a binary adder that takes into account two 4-bits numbers and returns their sum using an output variable. Implement both a bit-adder and the general adder as two separate modules.

# Exercise: Adder [2/3]

---

```
MODULE bit-adder(in1, in2, cin)
VAR
  sum : boolean;
  cout : boolean;
ASSIGN
  next(sum) := (in1 xor in2) xor cin;
  next(cout) := (in1 & in2) | ((in1 xor in2) & cin);

MODULE adder(in1, in2)
VAR
  bit[0] : bit-adder(in1[0], in2[0], bool(0));
  bit[1] : bit-adder(in1[1], in2[1], bit[0].cout);
  bit[2] : bit-adder(in1[2], in2[2], bit[1].cout);
  bit[3] : bit-adder(in1[3], in2[3], bit[2].cout);
DEFINE
  sum[0] := bit[0].sum;
  sum[1] := bit[1].sum;
  sum[2] := bit[2].sum;
  sum[3] := bit[3].sum;
  overflow := bit[3].cout;
```

# Exercise: Adder [3/3]

---

```
MODULE main
```

```
  VAR
```

```
    in1 : array 0..3 of boolean;  
    in2 : array 0..3 of boolean;  
    a : adder(in1, in2);
```

```
  ASSIGN
```

```
    next(in1[0]) := in1[0]; next(in1[1]) := in1[1];  
    next(in1[2]) := in1[2]; next(in1[3]) := in1[3];  
    next(in2[0]) := in2[0]; next(in2[1]) := in2[1];  
    next(in2[2]) := in2[2]; next(in2[3]) := in2[3];
```

```
  DEFINE
```

```
    op1 := toint(in1[0]) + 2*toint(in1[1]) + 4*toint(in1[2]) +  
          8*toint(in1[3]);  
    op2 := toint(in2[0]) + 2*toint(in2[1]) + 4*toint(in2[2]) +  
          8*toint(in2[3]);  
    sum := toint(a.sum[0]) + 2*toint(a.sum[1]) + 4*toint(a.sum[2]) +  
          8*toint(a.sum[3]) + 16*toint(a.overflow);
```

# Outline

1. Introduction
2. nuXmv interactive shell
3. nuXmv Modeling
4. Modules
5. Homework

## Homework 7.1: playing with Adder

- ▶ Simulate a random execution of the “adder” system;
- ▶ After how many steps the adder stores the computed final sum value? Is this number constant? Can you explain its behaviour?
- ▶ What happens if we initialize both `sum` and `cout` inside the bit-adder as `FALSE`? Can you explain which is the main difference with respect to the original algorithm?
- ▶ Can you modify the file in a simple way so that the sum is obtained after a single iteration? (PS: simple means you must modify/add less than 5 lines of code)
- ▶ Add a `reset` control which changes the values of the operands and restarts the computation of the sum

## Homework 7.2: random calculator

Use `nuXmv` to create a "random" calculator: it creates two random arrays of 3 integers numbers in the range  $[1,10]$ , then it randomly choose what operator apply for each pair of elements in the arrays (among sum, subtraction and multiplication) and store it in an output array of 3 elements called *res*. The results must be defined in 3 steps: in the first iteration you'll store the random operation between elements with index 0, in the second iteration the random operation between elements with index 1 and the same for the last index. Use an additional variable, *index*, to take into account this evolution.
